NASA SAMPLES FINAL REPORT

CONTRACT NAS9-15685

ORIGINAL PAGE IS
OF POOR QUALITY

1.0 INTRODUCTION

Under the NASA-JSC Contract NAS9-15685 the Vought Corporation was to fabricate Reinforced Carbon-Carbon (RCC) test samples and provide the necessary support to evaluate the results of the oxidation tests performed by NASA-LaRC. In addition, Vought was responsible for the mechanical testing to failure of a maximum of eighteen (18) tension specimens that had been exposed at NASA-LaRC to a combined environment of stress and oxidation simultaneously.

Modification 10C to this contract, effective 31 May 1982, authorized Vought to fabricate additional test specimens of Advanced Carbon Carbon (ACC). This effort is essentially limited to the fabrication and delivery of test specimens to NASA-JSC by 30 April 1983 with no follow-up test support or data evaluation planned.

This report is limited to the contractual items included in the basic contract plus Modifications 1S through 9S plus 11S thereby limiting it to the RCC material. Final reporting on the ACC material included in Modification 10C and 12S will be done separately at the conclusion of the ACC specimen fabrication.

The issuance of this final report satisfies and completes the requirements of Item 2 of this contract as defined in Modification 1S.

2.0 CONTRACT HISTORY/TASK DEFINITIONS

ORIGINAL PAGE IS
OF POOR QUALITY

The initiation of the basic contract was accomplished in August 1978 for the fabrication of forty-eight (48) RCC specimens. The eighteen (18) tension specimens were existing at the time, being supplied to NASA-LaRC under a separate contract. The contract modifications are listed below in chronological order with a brief description of the changes. The contract extensions identified below were made to allow completion of the tests at NASA-LaRC.

CONTRACT NAS9-15685 1 September 1978

- o Fixed Price Contract \$55,000
- o Exhibit A Statement of Work
 - Fabrication of forty-eight (48), thirty-eight (38) ply mechanical property specimens 17.0 centimeters x 4.3 centimeters (6.7 inches x 1.7 inches)
 - Performance of tension failing load tests on a maximum of eighteen (18) specimens
- o Completion date 31 January 1979

MODIFICATION 1S 8 January 1979

- o Contract extension to 30 April 1979

MODIFICATION 2S 1 May 1979

- o Contract extension to 31 October 1979

MODIFICATION 3S 16 November 1979

- o Contract value increased to \$75,525
- o Exhibit B Statement of Work
 - Additional requirements for forty-eight (48), 7.1 centimeters (2.8 inch) diameter plasma arc test specimens to be fabricated from nineteen (19) ply material
- o Contract extension to 31 October 1980

MODIFICATION 4S 12 December 1979

- o Contract extension to 1 July 1980

MODIFICATION 5S 29 July 1980

- o Contract extension to 29 July 1980

ORIGINAL PAGE IS
OF POOR QUALITY

MODIFICATION 6S 31 October 1980

- o Contract extension to 1 June 1981

MODIFICATION 7S 8 December 1980

- o Delivery addresses changed for reports

MODIFICATION 8S 31 May 1981

- o Contract extension to 15 January 1982

MODIFICATION 9S 15 January 1981

- o Contract extension to 1 July 1982

MODIFICATION 10C 31 May 1982

- o Exhibit C
 - Additional requirements to fabricate eight (8),
30.5 centimeters x 30.5 centimeters (12 inch x 12 inch)
ACC panels to be cut into test specimens

MODIFICATION 11S 1 July 1982

- o Contract extension to 1 October 1982

MODIFICATION 12S 1 June 1982

- o Contract value increased by \$49,140 for ACC panels

3.0 DISCUSSION

The forty-eight (48) test specimens identified in Exhibit A of the contract were fabricated from three existing panels transferred from a Rockwell contract Purchase Order M8J3XMS-483150D that had been previously terminated. Two of these panels (HP110 and HP113) were at the RCC-2 stage in the process cycle and the other one (HP116) was in the as-cured condition. Vought Engineering Release (ER) S1001.327 was issued to resume processing of these panels through machining, coating, and TEOS impregnation. These specimens were shipped to NASA-JSC on 15 January 1979, reference RFS-RCC-153

included in Enclosure (1). The specimen identification list and the documentation package for these specimens is also included in Enclosure (1). Eighteen (18) of these specimens were eventually returned to Vought for Type A coating. This was accomplished and the specimens shipped to NASA-LaRC on 7 January 1980 on RFS-RCC-193, a copy of which is included in Enclosure (1) along with a list of the specimens involved.

The combined environment test specimens were sent to Vought from NASA-LaRC and machined to the tension test configuration per ER S1001.363 in July 1979. The tension tests were performed in the Vought Structures Test Lab in August 1979 according to the requirements of Test Request 221TQ00789, a copy of which is included in Enclosure (2). The results of the tension tests are documented in Vought Design Information Release (DIR) 2-30400/RCC/9-0017 which is also included in Enclosure (2).

The minimum of twenty-seven (27) and maximum of forty-eight (48) plasma arc discs added to the contractual requirements by Modification 3S were started in fabrication in December 1979. Three panels (A306, A307, and A308) were fabricated per the instruction of ER S1001.377 through machining, Silicon Carbide Coating, and TEOS impregnation. Half of these specimens were coated with the Type A enhancement process. Thirty-eight (38) of these specimens, twenty (20) with Type A, were shipped to NASA-JSC on 27 June 1980 on RFS-RCC-210, a copy of which is included in Enclosure (3). The specimen identification and the certificate of compliance is also included in Enclosure (3). The remainder, a total of ten (10) specimens, were transferred to NASA-ARC under Purchase Order 71125B (LAM). These specimens were shipped to NASA-ARC on 4 August 1980 on RFS-RCC-218, a copy of which is included in Enclosure (3).

The radiant mass loss tests on the original set of RCC specimens were concluded at NASA-LaRC and the data sent to Vought in October 1982. This data has been documented and comparisons made with the previous February 1978 mass loss/mission life correlation in DIR 2-53200/RCC/2-0008. A copy of this document is included in Enclosure (4).

4.0 CONCLUSIONS/RECOMMENDATIONS

ORIGINAL PAGE IS
OF POOR QUALITY

The results of the combined environment tests and the radiant mass loss tests at NASA-LaRC were compatible with similar tests performed on RCC by other test agencies. The complex combined environment tests gave the same results as the simpler cyclic tests performed elsewhere. Also the radiant mass loss tests on both TEOS only and Type A coated specimens agreed with previous test data.

This report concludes the requirements of this contract on RCC Samples. There are no additional test data needed to supplement the current RCC data at this time. Future effort should be directed toward the next generation carbon material, ACC.

RCC specimens included in this shipment have been subjected to radiographic examination and ultrasonic inspection per Process Specification 208-7-40, 208-7-41 and 208-7-42 and accepted.

Coating thickness has been verified by Eddy Current technique and has been accepted with deviations noted in Deviation Summary.

1.0 PURPOSE

The purpose of the tests is to obtain the tensile strength of RCC material specimens that have been exposed to the combined environments of temperature, pressure and stress by LaRC.

2.0 DESCRIPTION OF SPECIMENS

Specimens will be fabricated by Manufacturing per the requirements of ER No. S1001.363. Test type, specimen identification and machine details are shown in Table 1.

3.0 TEST PROCEDURES AND DATA REQUIREMENTS

The test procedures and data requirements are the same as those outlined in the design allowables test requests shown in Table 1.

Flatness of each specimen is to be checked and any curvature of specimen is to be measured and recorded.

4.0 TEST SCHEDULE AND WITNESS

Test specimens will be supplied to the test laboratory by 1 August 1979. Tests will be performed on 7 August 1979. The test date is to agree with the date that Dr. D. R. Rummler from LaRC will be at Vought.

Tests will be witnessed by C. W. Payne, (Ext. 2149) and Dr. D. R. Rummler.

INTRODUCTION

Sixteen RCC tension specimens were loaded to failure on 7 and 8 August 1979. Testing was conducted at the Vought Corporation Structures and Systems Laboratories according to the instructions of Reference (a). Test specimens consisted of eight each of 19 ply and 33 ply material. Prior to the static tension failing load test the specimens were subjected to a combined temperature and pressure environment. One half of the specimens of each thickness were subjected to tensile stress in combination with the temperature and pressure environment. The 19 ply specimens were exposed to a high temperature profile with maximum temperature of 2480°F. The 33 ply specimens were exposed to a temperature profile with maximum temperature of 1115°F. The combined exposure tests for all specimens were conducted at Langley Research Center (LaRC).

DISCUSSION

After completion of the combined environment tests the specimens were delivered to Vought Corporation and final machined to the test configuration. A sketch of the specimen is shown in Figure I. Some of the 19 ply specimens were not completely flat with the maximum bow being .025 inches for specimen 39-6. While testing specimens 39-1, 39-2 and 39-3 it was discovered that the specimens were not seating properly in the loading blocks. The remaining specimens were returned to the machine shop and the radius reworked to improve the mating of the specimens to the loading blocks. Failure of all the specimens, except one, was similar in nature to failure of previously tested RCC tension specimens. Specimen 40-4 did not fail in tension in the straight section. Failure occurred as cracking of the coating and interlaminar shear of the substrate in the region of a loading block. As the failed specimens were returned to Dr. D. R. Rummel (LaRC) immediately after completion of the tests, very limited post test examination of the specimens were performed by Vought.

SUMMARY

Specimen identification, total coating thickness, mass loss and tension tests results are presented in Table I. The design allowables developed for RCC material used on the Space Shuttle Orbiter Wing Leading Edge and Nose Cap are normalized for a material coating thickness of 0.06 inches, total both sides.

In order to make a comparison of the test results and the LESS RCC design allowables, the test data tension strength of Table I was adjusted for a total coating thickness of 0.06 inches. Plots of the adjusted test values and LESS RCC design allowable "A" values are shown in Figure II. The design allowable "A" value represents a minimum guaranteed value having 99 percent probability and 95 percent confidence. As shown in Figure II no test specimen failed at a tension stress below the design allowable "A" value.

Subj: NASA Samples - Contract NAS9-15685

1.0 The contractual requirements of NAS9-15685, Modification 3S, specify the fabrication and delivery of a minimum of 27 and a maximum of 48 test specimens. A total of 38 specimens will be delivered, 18 specimens with TEOS only and 20 specimens with Type A Coating Enhancement.

2.0 The Quality Control log books will contain all of the pertinent process data and the control panel test results for the TEOS specimens. However, the Type A Coating Enhancement was applied to the specimens in the Engineering Test Lab and the formal paperwork for the control panel tests was not prepared for the log book. The current production specification was used and the Type A treated hardware delivered meets all current production specification requirements. The mass loss and flexure test data are included below from the Type A control panel tests:

| Specimen | Temp., °F | Time, Hrs. | Mass Loss, PSF | F _{bu} , PSI |
|----------|-----------|------------|----------------|-----------------------|
| E5 | 2300°F | 12 | -.0003 | 16,775 |
| E6 | 1000°F | 18 | .0662 | 10,067 |

M0991B

1.0 BACKGROUND

NASA-JSC contract NAS9-15685 with Vought Corporation was originally for the delivery of 48 reinforced carbon-carbon (RCC) test samples and the mechanical testing of 18 existing combined-environment tension specimens. The 48 specimens were for mass loss characteristic tests performed at NASA-LaRC under the direction of Dr. Donald M. Rummel. The basic contract has been modified several times to include application of Type A sealant to 18 of the 48 specimens, and more recently to fabricate advanced carbon-carbon (ACC) specimens.

This DIR deals only with a portion of this contract: the mass loss testing accomplished by NASA-LaRC on the majority of the 48 RCC test specimens.

2.0 SPECIMENS

The 48 RCC samples were rectangles (1.7" x 6.7") 19-ply thick. All were processed through the RCC densification steps, silicon carbide coated and TEOS impregnated (RCC/Coated/TEOS). Eighteen of the 48 specimens were later returned to Vought for incorporation of the Type A surface enhancement. These 18 specimens can be designated RCC/Coated/TEOS/Type A.

In terms of surface porosity, all 48 specimens tend toward being non-porous.

3.0 TEST CONDITIONS

Mass loss testing was accomplished in NASA-LaRC's multiple-parameter facility. Some mass loss conditioning was done at steady state conditions, that is, constant temperature and pressure. Other specimens were exposed to cyclical variations in temperature and pressure.

Three cyclic profiles were used. One with a peak temperature greater than 1000°F; one with a peak temperature greater than 1300°F; one with a peak temperature greater than 1600°F. These profiles were taken from the thermal analysis of the Shuttle wing 55% half span for the 14414.1C trajectory.

Nine separate steady state conditions were used: 0.1, 0.3 and 1.0 atmospheres pressure at temperatures of 1200°F, 1400°F and 1600°F.

In LaRC's multiple-parameter facility, two test specimens and a control specimen are exposed simultaneously. The control specimen is instrumented with thermocouple(s) for temperature measurement.

4.0 TEST RESULTS

NASA-LaRC furnished the mass loss data to Vought. These results are presented herein. The data taken during the cyclic exposure are presented in Figures 1 through 6. Figures 1 and 2 are the data taken during 100 cycles with a peak temperature of 1644°F. Figures 3 and 4 are the data taken over 100 cycles with a peak temperature of 1367°F. Figures 5 and 6 present the data taken during 100 cycles with a peak temperature of 1088°F. On each figure the data for one RCC/Coated/TEOS specimen and one RCC/Coated/TEOS/Type A specimen is plotted. Also plotted is the predicted mass loss based on Vought's mass loss correlation for RCC/Coated/TEOS material and measured temperatures and pressures.

Data taken at steady state conditions are presented in Figures 7 through 15. Again both TEOS and Type A specimens are shown with the correlation for TEOS treated material. Two Type A treated specimens are shown at 1400°F, 0.3 atmosphere and at 1600°F, 0.3 atmosphere.

5.0 DISCUSSION

The February 1978 correlation prediction plotted on each figure is based on RCC/Coated/TEOS material and should only be compared directly with the TEOS specimens. The TEOS specimen data are shown as circles on each figure. Looking first at the steady state data, there is good agreement between the TEOS specimen and the prediction at 1200°F, all pressures. At 1400°F there is good agreement at 0.3 atmosphere, but the prediction over predicts the mass loss of these individual specimens at 0.1 atmosphere and 1.0 atmosphere. At 1600°F there is good agreement at all pressures.

The mass loss of the Type A treated specimens is well below that of the non-Type A specimens at all temperatures and pressures.

In Figures 1 and 2 the correlation prediction under predicts the measured mass loss of the TEOS treated specimens exposed to the 1644°F peak temperature profile. The correlation is suspected to be in error at 1600°F because there was no 1600°F data used in the determination of the correlation constants. This is in the transition region between the rate controlled mass loss regime and the diffusion limited regime.

For the 1367°F peak temperature profile the February 1978 correlation again under predicts the measured mass loss, but not as much as at the higher temperature profile. The prediction catches up at about 95 cycles.

For the low-temperature profile (1088°F max), the prediction correlation over predicts the mass loss of specimen 13HP35 (Figure 5) and matches fairly well with the measured mass loss of specimen 10HP28 (Figure 6). This shows the scatter in the RCC/Coated/TEOS mass loss data.

NASA-LaRC made the following observations based on their examination of the specimens and data:

1. The Type A enhanced specimens are superior (lower mass loss) to the RCC/Coated/TEOS specimens in every case.
2. One Type A enhanced specimen did not exceed 0.10 pounds per square foot mass loss after 100 cycles to the most severe environment in the test series (1088°F peak temperature cycle).
3. The RCC/Coated/TEOS material maintained its integrity even after exceeding mass loss guide lines.
4. The data scatter appears to be less for the Type A enhanced specimens than for the RCC/Coated/TEOS material.
